

## Section 12.2 Notes: Features of Plate Tectonics

### Layers of the Earth

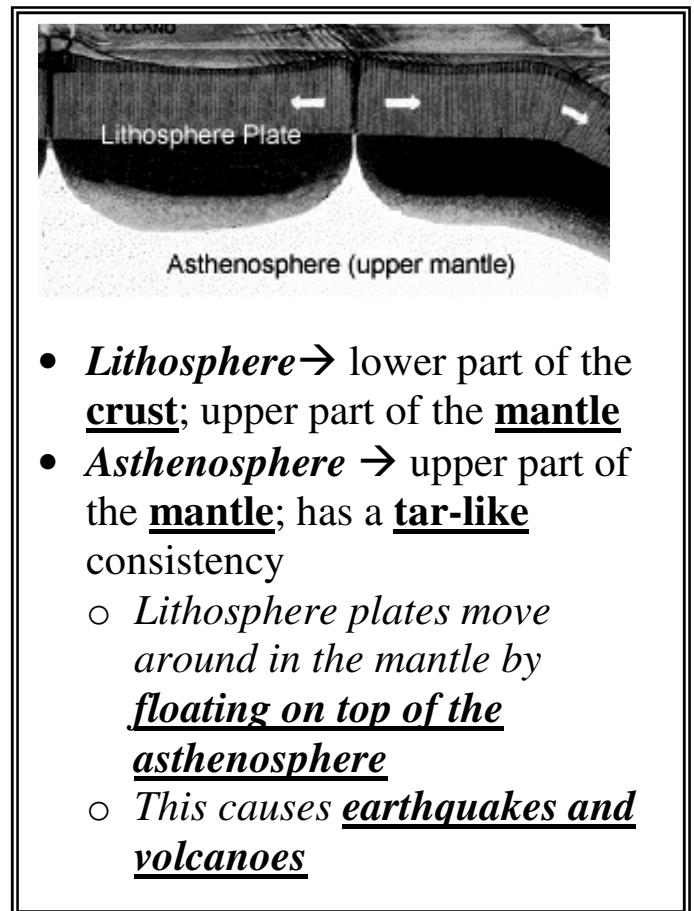

#### 1. Crust (Outermost; 0-100km thick)

- Consists of a series of **interlocking plates**
- **Thinnest layers** found under **oceans**, **thickest layers** found under **continents** (land)
- Continental crust tends to be made of **granite**, oceanic crust tends to be made of **basalt** (slightly denser than granite)
- Makes up ~ **1% of Earth's mass**

#### 2. Mantle (~ 2900km thick)

- Part **solid**, part **liquid**, Denser than the **crust layer**
- Most of the mantle is under **high pressure** and is **very hot**
- Accounts for ~ **70% of the Earth's mass**
- Behaves like a **thick liquid** (similar consistency to **tar**)
- **Convection currents** cause plates to move

#### Inner (~1250km thick) and Outer Core (~2200km thick)

- Thought to be mainly composed of **iron and nickel** with extremely **high temperature and pressure**
- Outer core → **Liquid** (molten = melted)
- Inner Core → **Solid**

- **Lithosphere** → lower part of the **crust**; upper part of the **mantle**
- **Asthenosphere** → upper part of the **mantle**; has a **tar-like consistency**
  - *Lithosphere plates move around in the mantle by **floating on top of the asthenosphere***
  - *This causes **earthquakes and volcanoes***

### Theory of Plate Tectonics

- The Earth's lithosphere is divided into a number of moving (~2cm/year) rigid pieces called **plates**. The study of **formation and movement** of these plates is known as **Plate Tectonics**

- The *Theory of Plate Tectonics* states that **lithospheric plates move around slowly** on the **fluid asthenosphere**, with the **plates interacting** when they **collide**
- If the plate is in an ocean, it is called an **Oceanic Plate**
- If the plate carries a continent, it is called a **Continental Plate**

### Plate Movement

- The lithospheric plates are believed to move due to **convection currents** in the **asthenosphere** (*Convection is the movement of heat*)
- The asthenosphere has a similar composition to the lithosphere, however, **it is partially melted and therefore has the ability to flow**

- As the **heated asthenosphere rises** to the **Earth's surface**, it pushes lithospheric plates **apart and begins to cool and solidify**, creating **new lithosphere** at areas called **RIDGES** (**spreading centres**)
- As the asthenosphere **cools**, the material becomes **denser and sinks back into the mantle**. Here, the lithospheric plates **move together** and form a **valley called a TRENCH**
- The latest tectonic theory states that a subducting plate is actually **pulling the rest of the plate into the asthenosphere** along with it. This process is referred to as a **"SLAB PULL"**

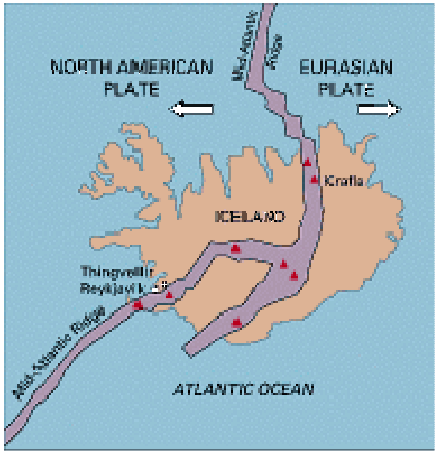

### Types of Plate Boundaries

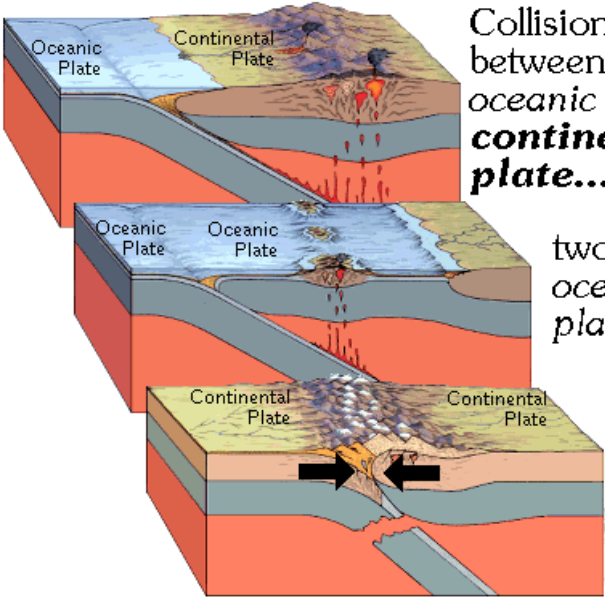

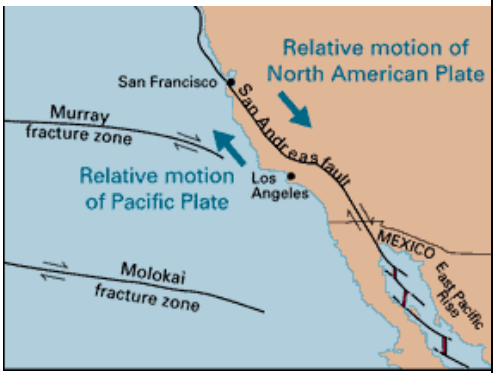

The **areas in which plates meet** are known as **Plate Boundaries**.

There are three types of plate boundaries:

- 1) **Diverging**
- 2) **Converging**
- 3) **Transform**

Type of Plate Boundary	Description	Image
<p><b>DIVERGING</b></p>	<ul style="list-style-type: none"> <li>• Where <b><u>two plates are moving apart</u></b> from one another</li> <li>• <b><u>Volcanoes</u></b> can occur here</li> <li>• a.k.a. <b><u>spreading centres</u></b></li> </ul> <p><b><u>Example: MidAtlantic Ridge</u></b></p>	 <p>The map shows the Mid-Atlantic Ridge, a divergent plate boundary, running north-south through the Atlantic Ocean. The North American Plate is on the left, and the Eurasian Plate is on the right. Iceland is shown as a volcanic island situated on the ridge. Other labels include Thingvellir, Reykjavik, and the Mid-Atlantic Ridge itself.</p>
<p><b>CONVERGING</b></p>	<ul style="list-style-type: none"> <li>• When two plates <b><u>come together (collide)</u></b></li> <li>• Often form <b><u>subduction zones</u></b>, where a <b><u>denser plate</u></b> (typically oceanic) is <b><u>forced underneath a less dense plate (trench formed)</u></b></li> <li>• <b><u>Or.....Formation of mountains</u></b> are found at these zones two plates move upwards</li> </ul>	 <p>The map illustrates the Cascadia Subduction Zone, a convergent plate boundary. The Juan de Fuca Plate is shown subducting beneath the North American Plate. Key locations labeled include Vancouver Island, Vancouver, Seattle, and Mount St. Helens. The map also shows the Columbia River and the boundaries of British Columbia, Canada, U.S., Washington, and Oregon.</p>

<p><b>Three Types of Convergent Plate Boundaries</b></p> <p><i>1 &amp; 2 – Volcanoes</i></p> <ul style="list-style-type: none"> <li>● <b>One plate is pushed down under the other</b> <i>3 – Mountains</i></li> <li>● <i>Both plates are forced upward</i></li> </ul>	 <p>Collisions can occur between one oceanic and one continental plate...</p> <p>two oceanic plates...</p> <p>or two continental plates.</p>
<p><b>TRANSFORM Fault</b></p>	<ul style="list-style-type: none"> <li>● Where two plates are <u>sliding past one another</u></li> <li>● a.k.a. <u>Sliding Boundaries</u></li> <li>● Where <u>earthquakes</u> occur</li> </ul> 

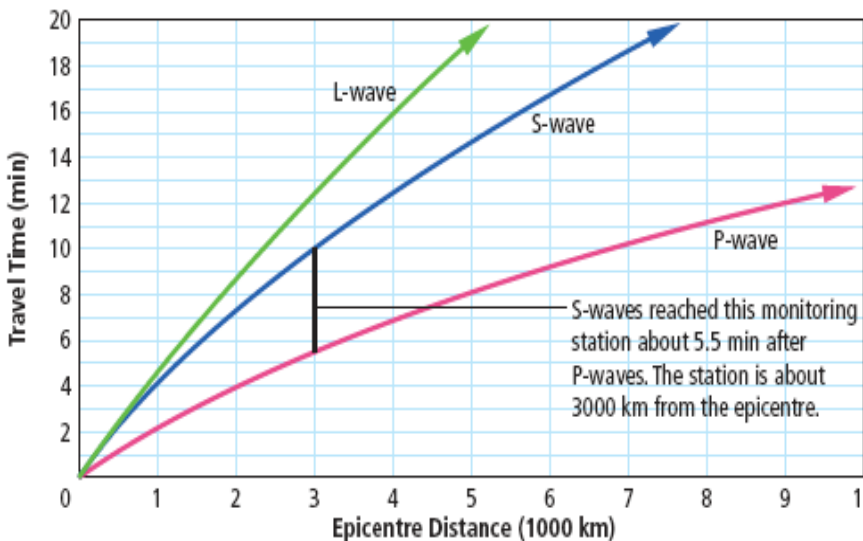

- Your *Data Booklet* provides information about where the various types of plate boundaries are located throughout the World

**Earthquakes**

- Earthquakes and volcanoes generally occur along plate boundaries
- Earthquakes detected by Seismographs
- Occur when plates move suddenly along faults
- Occur in waves called SEISMIC WAVES (P, S, & L). Can be BODY WAVES (TRAVEL UNDERGROUND) or a SURFACE WAVE (roll of earth's surface like ripples on a pond)
- Part of the fault where there is the most movement is the FOCUS

Type of Seismic Wave	Description
<b>P Wave</b> (Primary Wave)	<ul style="list-style-type: none"> <li><input type="checkbox"/> <b>BODY WAVE (GOES THROUGH ALL LAYERS OF EARTH INCLUDING CORE)</b></li> <li><input type="checkbox"/> <b>First to arrive and FASTEST</b></li> <li><input type="checkbox"/> <b>Travels through solids, liquids and gases</b></li> <li><input type="checkbox"/> <b>Travel through earth's crust at a rate of 6km/s</b></li> </ul>
<b>S Wave</b> (Secondary Wave)	<ul style="list-style-type: none"> <li><input type="checkbox"/> <b>BODY WAVE (CRUST AND MANTLE ONLY)</b></li> <li><input type="checkbox"/> <b>Second to arrive (slower than P waves, travel at about 3.5 km/s)</b></li> <li><input type="checkbox"/> <b>Waves are "larger" so greater damage to structures during earthquake</b></li> <li><input type="checkbox"/> <b>Travels through solids but not liquids</b></li> </ul>
<b>L Wave</b> (Surface waves)	<ul style="list-style-type: none"> <li><input type="checkbox"/> <b>SURFACE WAVE (CRUST ONLY)</b></li> <li><input type="checkbox"/> <b>Travels along Earth's surface ONLY</b></li> <li><input type="checkbox"/> <b>Last to arrive (slowest)</b></li> <li><input type="checkbox"/> <b>Roll along earth's surface like ripples in a pond</b></li> </ul>

Time-Distance Graph for Seismic Waves

- Point on the surface of the crust directly above the focus is called the **Epicenter** (it is the location where the earthquake feels the strongest)

- Earthquakes result when **stress begins to build up** between two plates.
- This initial stress **does not usually cause any movement** of the plate, because **friction** between the plates **hold them together at the plate boundary**
- Eventually, this stress can cause **deformation of the plates**
- If the stress gets large enough it **overcomes the force of friction**, resulting in the **sudden movement** of the plates
- Once this occurs, the plates **snap back into shape, but in new locations relative to one another**
- *This particular explanation for the occurrence of earthquakes is known as the **Elastic-Rebound Theory***
- Anytime an earthquake occurs under the ocean, a tsunami (giant wave) may occur, travelling at speeds up to 800km/hour.

## Volcanoes

- When a volcano erupts, an **earthquake always occurs**
- There are 3 types of volcanoes: **composite, shield, and rift eruptions**
- Most of the Earth's earthquakes and volcanoes **occur along the boundaries between lithospheric plates**
- Some volcanoes, however, occur in the **center of lithospheric plates**
- These areas are called **Hot Spots**. The **Hawaiian Islands** formed due to one such hot spot
- A hot spot is believed to occur due to **concentrations of heat from radioactive sources in the asthenosphere**
